

Relay Protection TCC Curve

Overview

Time-current curves (commonly abbreviated T-C curves or TCC) are the graphical language of protection engineers. Discrimination, also called selectivity, is the coordination between series-connected protective devices so that only the device nearest the fault operates, leaving upstream circuits unaffected. IEC 60947-2 Annex A defines methods for verifying full and partial discrimination using time-current. The Time-Current Curves for cables are also known as “Damage” curves. What would cause a fuse to blow?

Refer to NEC Article 430. The curves rely on the physical characteristics and construction of the protective device, as well as the selected settings for applicable. Online relay coordination platform for overcurrent and earth-fault studies, interactive TCC curves, dynamic single-line diagrams, transformer inrush, fault simulation, voltage calculations, professional reports, cloud storage and Excel export. Supports LV to transmission voltage levels with 5 professional presets and exportable coordination.
